International Research Forum on Monetary Policy: Third Conference

This paper was presented at the third conference of the International Research Forum on Monetary Policy which took place on May 20-21, 2005 at the ECB. The Forum is sponsored by the European Central Bank, the Board of Governors of the Federal Reserve System, the Center for German and European Studies at Georgetown University and the Center for Financial Studies at Goethe University. Its purpose is to encourage research on monetary policy issues that are relevant from a global perspective. It regularly organises conferences held alternately in the Euro Area and the United States. The conference organisers were Ignazio Angeloni, Matt Canzoneri, Dale Henderson, and Volker Wieland. The conference programme, including papers and discussions, can be found on the ECB's web site (<http://www.ecb.int/events/conferences/html/intforum3.en.html>)

Abstract

Does an inflation conservative central bank à la Rogoff (1985) remain desirable in a setting with endogenous fiscal policy? To provide an answer we study monetary and fiscal policy games without commitment in a dynamic stochastic sticky price economy with monopolistic distortions. Monetary policy determines nominal interest rates and fiscal policy provides public goods generating private utility. We find that lack of fiscal commitment gives rise to excessive public spending. The optimal inflation rate internalizing this distortion is positive, but lack of monetary commitment robustly generates too much inflation. A conservative monetary authority thus remains desirable. Exclusive focus on inflation by the central bank recoups large part - in some cases all - of the steady state welfare losses associated with lack of monetary *and* fiscal commitment. An inflation conservative central bank tends to improve also the conduct of stabilization policy.

Keywords: sequential non-cooperative policy games, discretionary policy, time consistent policy, conservative monetary policy

JEL Classification: E52, E62, E63

Non-Technical Summary

The pitfalls associated with day-to-day decision making in economic policy have occupied economists ever since the seminal contribution by Kydland and Prescott (1977). They show that even well-intended policymakers, i.e., policymakers pursuing socially desirable objectives, may deliver suboptimal policy outcomes, if they determine their policies period-by-period rather than sufficiently far in advance.

The reason for this finding is simple: the policy problem for period zero looks different than the one for later periods because of a forward-looking private sector. While future policy decisions affect today's expectations and thereby current private sector decisions, current policy decisions do not affect past decisions anymore. Since every period looks like period zero with day-to-day policymaking, this results in suboptimal policy outcomes from an ex-ante perspective.

Probably the most well-known example for a suboptimal policy outcome is the so-called 'inflation bias' associated with the day-to-day conduct of monetary policy, see Barro and Gordon (1983). In period zero the monetary policymaker is willing to accept some inflation so as to increase output. Since every period appears to be period zero with sequential policymaking and since the private sector will eventually understand this, the outcome is inflation only but no increase in output, causing the policy to become self-defeating.

Many solutions have been proposed to overcome the monetary commitment problem. A particularly well-known proposal is due to Rogoff (1985) who suggested installing an inflation conservative central bank, i.e., a monetary authority that dislikes inflation more than is suggested by social preferences. Rogoff's analysis abstracts, however, from the conduct of fiscal policy.

This paper asks the question of whether the desirability of an inflation conservative central bank extends to a setting in which fiscal policy might react to the way monetary policy is conducted. This question is by no means trivial. As we show, it ceases to be optimal to implement strict price stability once the presence of day-to-day fiscal policymaking is taken into account. Quantitatively, however, price stability remains close to optimal and so does installing an inflation conservative central bank. Indeed, it seems optimal to have a central bank that cares predominantly about inflation and only to a lesser degree about other objectives. In particular, a central bank focusing on inflation exclusively may not only remedy the distortions associated with day-to-day monetary policymaking but also those associated with day-to-day fiscal policymaking. In this sense, the case for an inflation conservative central bank can become even stronger once fiscal policy is taken into account.

1 Introduction

The difficulties associated with executing optimal but time-inconsistent policy plans have received much attention following the seminal work of Kydland and Prescott (1977) and Barro and Gordon (1983). Time inconsistency problems, however, have hardly been analyzed in a dynamic setting where monetary and fiscal policymakers are separate authorities engaged in a non-cooperative policy game. This may appear surprising given that the institutional setup in most developed countries suggests such an analysis to be of relevance.

In this paper we analyze non-cooperative monetary and fiscal policy games assuming that policymakers cannot commit to future policy choices. We start by identifying the policy biases emerging from sequential and non-cooperative decision making and study how these biases interact with each other. Then we provide a normative analysis assessing the implications of installing a central bank that is conservative in the sense of Rogoff (1985).¹ In other terms, we analyze the desirability of central bank conservatism in a setting with endogenous fiscal policy.

Presented is a dynamic stochastic sticky price economy without capital along the lines of Rotemberg (1982) and Woodford (2003) in which output is inefficiently low due to market power by firms. The economy features two independent policymakers, i.e., a fiscal authority deciding about the level of public goods provision and a monetary authority determining the short-term nominal interest rate. Public goods generate utility for private agents and are financed by lump sum taxes, so as to balance the government's intertemporal budget constraint. Monetary and fiscal authorities are assumed benevolent, i.e., they maximize the utility of the representative agent.

The natural starting point for our analysis is the Ramsey allocation, which assumes full policy commitment and cooperation among monetary and fiscal policymakers. The Ramsey allocation is second-best, it thus provides a useful benchmark against which one can assess the welfare costs of sequential and non-cooperative policymaking. The Ramsey steady state is characterized by price stability and public spending below the first-best level. Public spending below the first-best is optimal because it reduces the marginal disutility of labor and thereby helps sustain private consumption, which is inefficiently low because of the wedge created by firms' monopoly power.

However, the Ramsey outcome is unattainable because monetary and fiscal authorities both face a time-inconsistency problem in the presence of sticky prices and monopolistic competition. While price setters are forward-looking, policymakers that decide sequentially fail to perceive the implications of their current policy decisions on past price setting decisions, since past prices can

¹Walsh (1995) and Svensson (1997) discuss alternative institutional arrangements for overcoming the problems related to the lack of monetary commitment.

be taken as given at the time policy is determined. As a result, policymakers underestimate the welfare costs of generating inflation today and try to move output closer to its first-best level.

We find that lack of monetary commitment gives rise to an inflation bias, as in the standard setting with exogenous fiscal policy. More importantly - and to our knowledge new to the literature - we show that lack of fiscal commitment gives rise to a fiscal spending bias, i.e., overspending on public goods. In particular, in the presence of price stability the fiscal authority implements the first-best level of public spending, which is suboptimally high. We also show that, taking the lack of fiscal commitment as given, it is optimal for monetary policy to implement positive inflation rates, as these reduce the fiscal spending bias and thereby increase agents' utility. Thus, unlike in the standard case with exogenous fiscal policy, price stability ceases to be optimal in a setting with endogenous fiscal policy! These results are proved analytically.

The desirability of a conservative or liberal central bank is a quantitative issue that depends on whether the optimal inflation rate that internalizes its effects on fiscal policy is above or below the monetary inflation bias emerging in the absence of commitment. If the optimal inflation rate is below (above) the monetary inflation bias, an inflation conservative (liberal) central bank is desirable.

To investigate this issue we start by characterizing the non-cooperative Markov-perfect Nash equilibrium, in which both policymakers determine their policies sequentially.² For our baseline calibration and a central bank maximizing social welfare, this equilibrium features a monetary inflation bias as well as a government spending bias and significant welfare losses, compared to the Ramsey allocation. Moreover, the optimal inflation rate turns out to be well below the inflation rate emerging in equilibrium. These findings are robust to a wide range of alternative model parameterizations and suggest installing a conservative monetary authority to be desirable.

We then consider a conservative central bank that maximizes a weighted sum of an inflation loss term and the representative agent's utility, and study the resulting Markov-perfect equilibria. An appropriate degree of monetary conservatism eliminates large part of the steady state welfare losses associated with lack of monetary and fiscal commitment. Interestingly, the welfare gains depend in a highly nonlinear fashion on the degree of monetary conservatism. While a fully conservative central bank, i.e., an authority focusing exclusively on price stability, is close to optimal, insufficient focus on inflation gives quickly rise to substantial welfare losses.

When fiscal policy is determined before monetary policy in each period, a fully conservative monetary authority eliminates the steady state distortions

²Markov-perfect Nash equilibria are a standard refinement used in the applied dynamic games literature, e.g., Klein et al. (2004).

associated with lack of monetary *and* fiscal commitment, i.e., achieves the Ramsey steady state allocation. The case for a conservative central bank may thus appear even stronger once endogenous fiscal policy is considered.

We also study how the conduct of stabilization policy is affected by the installation of a conservative central bank. Interestingly, a conservative central bank tends to improve stabilization policy, compared to a central bank that maximizes social welfare instead. In particular, we show that full conservatism causes the policy response to technology shocks to become optimal, i.e., identical to that under Ramsey policy. Results for mark-up shocks are less clear and partly depend on the timing of policy moves.

The remainder of this paper is structured as follows. After discussing the related literature in section 2, section 3 introduces the economic model and derives the implementability constraints for the private sector. Section 4 considers monetary and fiscal policy with and without commitment, derives analytical results about the policy biases resulting from lack of commitment, and discusses how these biases interact with each other. After calibrating the model in section 5, section 6 provides a quantitative assessment of the steady state effects generated by sequential policymaking. Section 7 introduces a conservative central bank and analyzes the steady state effects of monetary conservatism. The effects on stabilization policy are discussed in section 8. A conclusion briefly summarizes the results and provides an outlook for future work. Technical material is contained in the appendix.

2 Related Literature

Problems of optimal monetary and fiscal policy are traditionally studied within the optimal taxation framework introduced by Frank Ramsey (1927). In the so-called Ramsey literature, monetary and fiscal authorities are treated as a ‘single’ authority and decisions are taken at time zero, e.g., Chari and Kehoe (1999).³ In seminal contributions, Kydland and Prescott (1977) and Barro and Gordon (1983) show that time zero optimal choices might be time-inconsistent, i.e., reoptimization in successive periods would imply a different policy to be optimal than the one initially envisaged.

The monetary policy literature has extensively studied time-inconsistency problems in dynamic settings and potential solutions to it, e.g., Rogoff (1985), Svensson (1997) and Walsh (1995). However, in this literature fiscal policy is typically absent or assumed exogenous to the model. Similarly, a number of contributions analyze sequential fiscal decisions and the time-consistency of optimal fiscal plans in dynamic general equilibrium models, e.g., Lucas and

³Galí and Monacelli (2005) extend the Ramsey approach to the case of a monetary union, i.e., an environment with a single monetary authority but many fiscal decision makers.

Stokey (1983), Chari and Kehoe (1990) or Klein, Krusell, and Ríos-Rull (2004). This literature typically studies models without money.

An important strand of the literature, developed by Sargent and Wallace (1981), Leeper (1991), and Woodford (2001), studies monetary and fiscal policy interactions using policy rules, e.g., Schmitt-Grohé and Uribe (2004b) and Ferrero (2005). This literature, however, does not consider time-inconsistency problems, as it assumes policymakers to be fully committed to simple rules.

A range of papers discusses monetary and fiscal policy interactions with and without commitment in a static framework where monetary and fiscal policymakers interact only once, e.g., Alesina and Tabellini (1987). This paper goes beyond these earlier contributions by studying a fully dynamic and stochastic model where current economic outcomes are influenced also by expectations about the future. This is similar in spirit to a recent paper by Díaz-Giménez et al. (2006) which determines sequential optimal policy in a fully dynamic cash-in-advance economy with government debt. While they study a flexible price model in which interactions between monetary and fiscal policy operate through seigniorage and the government budget constraint, we abstract from seigniorage as a source of government revenue. Instead, we focus on the interactions arising from the presence of nominal rigidities.

3 The Economy

In the next sections we first introduce a sticky-price economy model, similar to the one studied in Schmitt-Grohé and Uribe (2004a), then we derive the private sector equilibrium for different monetary and fiscal policy regimes.

3.1 Private Sector

There is a continuum of identical households with preferences given by

$$E_0 \sum_{t=0}^{\infty} \beta^t u(c_t, h_t, g_t) \quad (1)$$

where c_t denotes consumption of an aggregate consumption good, $h_t \in [0, 1]$ labor effort, g_t public goods provision by the government in the form of aggregate consumption goods, and $\beta \in (0, 1)$ the subjective discount factor. Throughout the paper we assume:

Condition 1 $u(c, h, g)$ is separable in (c, h, g) , and $u_c > 0$, $u_{cc} < 0$, $u_h < 0$, $u_{hh} \leq 0$, $u_g > 0$, $u_{gg} < 0$, and $\left| \frac{cu_{cc}}{u_c} \right|, \left| \frac{hu_{hh}}{u_h} \right|$ bounded for all $(c, h, g) \in [0, 1]$.

Each household produces a differentiated intermediate good. Demand for this intermediate good is given by

$$y_t d\left(\frac{\tilde{P}_t}{P_t}\right)$$

where y_t denotes (private and public) demand for the aggregate good, \tilde{P}_t is the nominal price of the good produced by the household, and P_t is the nominal price of the aggregate good. The demand function $d(\cdot)$ satisfies

$$\begin{aligned} d(1) &= 1 \\ d'(1) &= \eta_t \end{aligned}$$

where $\eta_t \in (-\infty, -1)$ is the price elasticity of demand for the different goods. This elasticity is assumed to be time-varying and induces fluctuations in the monopolistic mark-up charged by firms. The household chooses \tilde{P}_t , then hires the necessary amount of labor effort \tilde{h}_t to satisfy the resulting product demand, i.e.,

$$z_t \tilde{h}_t = y_t d\left(\frac{\tilde{P}_t}{P_t}\right) \quad (2)$$

where z_t denotes an aggregate technology shock. We assume the mark-up shock and the technology shock to follow AR(1) stochastic processes, respectively,

$$\begin{aligned} \eta_t &= \eta(1 - \rho_\eta) + \rho_\eta \eta_{t-1} + \varepsilon_{\eta t} \\ z_t &= (1 - \rho_z) + \rho_z z_{t-1} + \varepsilon_{z t} \end{aligned}$$

where $\eta < -1$ denotes the steady value of the price elasticity of demand, and the innovations ε_{it} ($i = \eta, z$) are mean zero, independent both across time and cross-sectionally, with small bounded support.

Following Rotemberg (1982), we describe sluggish nominal price adjustment by assuming that firms face quadratic resource costs for adjusting prices according to

$$\frac{\theta}{2} \left(\frac{\tilde{P}_t}{\tilde{P}_{t-1}} - 1 \right)^2$$

where $\theta > 0$ measures the degree of price stickiness. The flow budget constraint of the household is given by

$$P_t c_t + B_t = R_{t-1} B_{t-1} + P_t \left[\frac{\tilde{P}_t}{P_t} y_t d_t \left(\frac{\tilde{P}_t}{P_t} \right) - w_t \tilde{h}_t - \frac{\theta}{2} \left(\frac{\tilde{P}_t}{\tilde{P}_{t-1}} - 1 \right)^2 \right] + P_t w_t h_t - P_t l_t \quad (3)$$

where R_t is the gross nominal interest rate, B_t denotes nominal bonds that pay $R_t B_t$ in period $t + 1$, w_t is the real wage paid in a competitive labor market, and l_t are lump sum taxes.

Although bonds are the only available financial instrument, assuming complete financial markets instead would make no difference for the analysis, since households have identical incomes in a symmetric price setting equilibrium. One should note that we abstract from money holdings. This can be interpreted as the ‘cashless limit’ of a model economy with money, see Woodford (1998). Money thus imposes only a lower bound on the nominal interest rate, i.e., $R_t \geq 1$, each period.⁴

Finally, we impose a no-Ponzi scheme borrowing constraint on household behavior

$$\lim_{j \rightarrow \infty} E_t \prod_{i=0}^{t+j-1} \frac{1}{R_i} B_{t+j} \geq 0 \quad (4)$$

that has to hold each period and at all contingencies.

The household’s problem consists of choosing $\{c_t, h_t, \tilde{h}_t, \tilde{P}_t, B_t\}_{t=0}^{\infty}$ so as to maximize (1) subject to (2), (3) and (4) taking as given $\{y_t, P_t, w_t, R_t, g_t, l_t\}_{t=0}^{\infty}$. Using equation (2) to substitute \tilde{h}_t in (3) and letting the multiplier on (3) be $\frac{\lambda_t}{P_t}$, the first order conditions of the household’s problem are then equations (2), (3) and (4) holding with equality and also

$$\begin{aligned} u_{ct} &= \lambda_t \\ -\frac{u_{ht}}{u_{ct}} &= w_t \\ \frac{\lambda_t}{R_t} &= \beta E_t \frac{\lambda_{t+1}}{\Pi_{t+1}} \end{aligned} \quad (5)$$

$$\begin{aligned} 0 &= \lambda_t \left[y_t d(r_t) + r_t y_t d'(r_t) - \frac{w_t}{z_t} y_t d'(r_t) - \theta \left(\Pi_t \frac{r_t}{r_{t-1}} - 1 \right) \frac{\Pi_t}{r_{t-1}} \right] \\ &+ \beta \theta E_t \lambda_{t+1} \left(\frac{r_{t+1}}{r_t} \Pi_{t+1} - 1 \right) \frac{r_{t+1}}{r_t^2} \Pi_{t+1} \end{aligned}$$

where $r_t \equiv \frac{\tilde{P}_t}{P_t}$ denotes the relative price and $\Pi_t \equiv \frac{P_t}{P_{t-1}}$ is the gross consumer price inflation rate. Furthermore, there is the transversality condition

$$\lim_{j \rightarrow \infty} E_t \beta^{t+j} \frac{u_{ct+j} B_{t+j}}{P_{t+j}} = 0 \quad (6)$$

which has to hold each period and at all contingencies.

⁴ Abstracting from money entails that we ignore possible seigniorage revenues generated in the presence of positive nominal interest rates. Since we allow for lump sum taxes, one can safely ignore the fiscal implications of such revenues.

3.2 Government

The government consists of two authorities, i.e., a monetary authority setting short-term nominal interest rates and a fiscal authority deciding on government expenditures and lump sum taxes.

Government expenditures consist of spending related to the provision of public goods g_t and socially wasteful expenditure x that does not generate utility for private agents. The level of public goods provision g_t is a choice variable, while x is taken to be exogenous. The government's budget constraint is then given by

$$B_t = R_{t-1}B_{t-1} + P_t(g_t + x - l_t) \quad (7)$$

The financing decisions of the government, i.e., tax versus debt financing, do not matter for equilibrium determination, since Ricardian equivalence applies as long as the implied paths for the debt level satisfy the no-Ponzi scheme borrowing constraint (4) and the transversality condition (6) at all contingencies. For sake of simplicity, we assume taxes to be set such that the level of real debt $\frac{B_t}{P_t}$ remains always positive and grows asymptotically at a rate less than $\frac{1}{\beta}$. Constraints (4) and (6) are then always satisfied and can be ignored from now on. Fiscal policy is thus 'passive' in the sense of Leeper (1991).

3.3 Private Sector Equilibrium

In a symmetric price setting equilibrium the relative price is given by $r_t = 1$ for all t . From the assumptions made in the previous section, it follows that the first order conditions of households behavior can be condensed into a price setting equation

$$u_{ct}(\Pi_t - 1)\Pi_t = \frac{u_{ct}z_t h_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} \right) + \beta E_t u_{ct+1}(\Pi_{t+1} - 1)\Pi_{t+1} \quad (8)$$

and a consumption Euler equation

$$\frac{u_{ct}}{R_t} = \beta E_t \frac{u_{ct+1}}{\Pi_{t+1}} \quad (9)$$

A rational expectations equilibrium is then a set of plans $\{c_t, h_t, B_t, P_t\}$ satisfying equations (8) and (9), the government budget constraint (7), and the market-clearing condition

$$z_t h_t = c_t + \frac{\theta}{2}(\Pi_t - 1)^2 + g_t + x \quad (10)$$

given the policies $\{g_t, l_t, R_t \geq 1\}$, the value of x , the exogenous stochastic processes $\{\eta_t, z_t\}$, and the initial conditions $R_{-1}B_{-1}$ and P_{-1} .

4 Monetary and Fiscal Policy Regimes

In this section we study the outcomes associated with different degrees of commitment in monetary and fiscal policy. The main focus is on the steady state implications of the different policy regimes. The impulse responses to mark-up and productivity shocks will be considered in section 8.

It turns out useful to start by analyzing the first-best allocation, i.e., the allocation that would be achieved in the absence of monopoly distortions and nominal rigidities. In a second step we consider the Ramsey allocation, which takes into account both distortions, but assumes commitment to policies at time zero. In a final step we relax the assumption of policy commitment.

4.1 First-Best Allocation

The first-best allocation solves

$$\begin{aligned} \max_{\{c_t, h_t, g_t\}} E_0 \sum_{t=0}^{\infty} \beta^t u(c_t, h_t, g_t) \\ \text{s.t.} \\ z_t h_t = c_t + g_t + x \end{aligned} \quad (11)$$

where equation (11) is the resource constraint. The steady state first-order conditions deliver

$$u_c = u_g = -u_h$$

showing, as expected, that it is optimal to equate the marginal utility of private and public consumption to the marginal disutility of labor effort. The next section shows that this ceases to be optimal once distortions are taken into account.

4.2 Ramsey Policy

Assuming commitment to policies at time zero and full cooperation between monetary and fiscal policymakers, the Ramsey allocation solves⁵

$$\begin{aligned} \max_{\{c_t, h_t, \Pi_t, R_t \geq 1, g_t\}} E_0 \sum_{t=0}^{\infty} \beta^t u(c_t, h_t, g_t) \\ \text{s.t.} \end{aligned} \quad (12)$$

Equations (8), (9), (10) for all t

The Ramsey planner maximizes the utility function of the representative agent subject to the implementability constraints (8) and (9), which summarize the

⁵Since Ricardian equivalence holds we ignore the financing decisions of the fiscal authority and the initial debt level $R_{-1}B_{-1}$, which do not matter for equilibrium determination of the other variables. Since the initial condition P_{-1} simply normalizes the implied price level path, it can equally be ignored.

price setting and monopoly distortion in the economy, the feasibility constraint (10), and the lower bound on nominal interest rates.⁶ As shown in appendix A.1, the Ramsey steady state is characterized by

$$\begin{aligned}\Pi &= 1 \\ R &= \frac{1}{\beta}\end{aligned}$$

the feasibility constraint (10) and the marginal conditions

$$u_c = -\frac{\eta}{1+\eta}u_h \quad (13)$$

$$u_g = -\frac{1+\frac{\eta}{1+\eta}q}{1+q}u_h \quad (14)$$

where $q \equiv -\frac{c}{h}\frac{hu_{hh}}{u_h}\frac{u_c}{cu_{cc}} \geq 0$. Equation (13) shows that in the presence of monopolistic competition ($\eta > -\infty$) it ceases to be optimal to equate the marginal utility of private consumption to the marginal disutility of labor effort. This reflects the labor supply distortion induced by firms' monopoly power.⁷ Equation (14) shows that, provided $q > 0$, it is also suboptimal to equate the marginal utility of public consumption to the marginal disutility of labor effort. Both these effects work in the direction of reducing private and public consumption, compared to their first best level.

In the special case of linear labor disutility, i.e., $u_{hh} = 0$, one has $q = 0$ and it remains optimal to set $u_g = -u_h$ despite the presence of monopolistic competition. The optimal provision of public goods is then given by its first-best level. Instead, if $u_{hh} < 0$, lowering the level of public consumption reduces u_h and thereby helps to sustain private consumption. This makes it optimal to reduce fiscal spending below its first-best level, a feature that will prove to be important subsequently.

4.3 Sequential Policymaking

We now consider separate monetary and fiscal authorities that cannot commit to future policy plans, instead they decide policies at the time of implementation, i.e., period-by-period. To facilitate the exposition, we assume that a sequentially deciding policymaker takes as given the current policy choice of the other policymaker as well as all future policies and future private sector choices. We prove the rationality of this assumption at the end of this section.

⁶In what follows, we abstract from the non stationary component of time zero optimal policies. In our numerical application we ascertain that the time zero commitment policies asymptotically approach the steady states values reported below and also verify that the non stationary component does not alter the welfare conclusions.

⁷From equations (5) and (13), it follows that $w = \frac{1+\eta}{\eta} < 1$ in steady state, i.e., real wages fall short of their marginal product.

4.3.1 Sequential Fiscal Policy

Consider sequential fiscal policymaking. Given the assumptions made above, the fiscal authority's problem in period t is

$$\begin{aligned} \max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, g_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j u(c_{t+j}, h_{t+j}, g_{t+j}) \quad (15) \\ \text{s.t.} \\ \text{Equations (8), (9), (10) for all } t \\ \{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j-1} \geq 1, g_{t+j}\} \text{ given for } j \geq 1 \end{aligned}$$

As shown in appendix A.2, the first order conditions associated with problem (15) deliver the fiscal reaction function

$$u_{gt} = -\frac{u_{ht}}{z_t} \frac{2\Pi_t - 1}{2\Pi_t - 1 - (\Pi_t - 1)(1 + \eta_t + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t})} \quad (\text{FRF})$$

where the fiscal authority sets the level of public goods provision g_t such that FRF is satisfied, each period.

Consider a steady state in which $\Pi = 1$, i.e., with an inflation rate equal to the one chosen by the Ramsey planner. The fiscal reaction function then simplifies to

$$u_g = -u_h \quad (16)$$

showing that fiscal policy equates the marginal utility of public consumption to the marginal disutility of labor effort. While such behavior is consistent with the first-best allocation, it is generally suboptimal in the presence of monopolistic distortions, see equation (14). Sequential fiscal policy implies a suboptimally high level of public spending, i.e., a 'fiscal spending bias'. This spending bias causes the Ramsey allocation to be unattainable in the presence of sequential fiscal policy, because either inflation, fiscal spending, or both must deviate from their Ramsey values. This is summarized in the following proposition.

Proposition 1 *For $u_{hh} < 0$, sequential fiscal policy implies excessive fiscal spending in the presence of price stability.*

The economic intuition underlying this result is as follows. By taking future decisions and the current monetary policy choice R_t as given, the fiscal authority considers private consumption c_t to be determined by the Euler equation (9). Given this, the fiscal authority perceives labor input h_t to move one-for-one with government spending g_t . In a situation with price stability, the inflation costs of public spending are zero (at the margin) and can be ignored. This causes the sequential spending rule (16) to appear optimal. In the general case $\Pi \neq 1$, the marginal costs of inflation fail to be zero, leading to the more general expression given in FRF.

4.3.2 Sequential Monetary Policy

We now consider sequential monetary policy. Given the assumptions made above, the monetary authority's problem in period t is

$$\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1\}} E_t \sum_{j=0}^{\infty} \beta^j u(c_{t+j}, h_{t+j}, g_{t+j}) \quad (17)$$

s.t.

Equations (8),(9),(10) for all t

$\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j-1}\}$ given for $j \geq 1$

As shown in appendix A.3, the first order conditions associated with problem (17) deliver the monetary reaction function

$$\begin{aligned} & -\frac{z_t u_{ct}}{u_{ht}} (\eta_t (\Pi_t - 1) - \Pi_t) - (\Pi_t - 1) \eta_t \left(1 + h_t \frac{u_{hht}}{u_{ht}} \right) \\ & + 2\Pi_t - 1 - \frac{u_{cct}}{u_{ct}} (\Pi_t - 1) (\theta(\Pi_t - 1)\Pi_t - z_t h_t (1 + \eta_t)) = 0 \end{aligned} \quad (\text{MRF})$$

where the monetary authority sets the nominal interest rate R_t such that MRF is satisfied, each period. Appendix A.4 proves the following result.

Proposition 2 *For β sufficiently close to 1, sequential monetary policy implies a strictly positive rate of inflation in steady state.*

Sequential monetary policy thus generates an inflation bias as in the standard case with exogenous fiscal policy, e.g., Svensson (1997). Intuitively, the monetary authority is tempted to stimulate demand by lowering nominal interest rates. Since price adjustments are costly, the price level will not fully adjust, real interest rates fall, stimulating demand. The real wage increase required to satisfy this additional demand generates inflation, but the welfare costs of inflation are not fully taken into account for reasons discussed before.

4.3.3 Sequential Monetary and Fiscal Policy

We now define a Markov-perfect Nash equilibrium with sequential monetary and fiscal policy. We start by verifying the rationality of our initial assumption that a sequentially deciding policymaker takes as given the current policy choice of the other policymaker, as well as all future policies and future private sector decisions.

The private sector's optimality conditions (8) and (9), the feasibility constraint (10), as well as the policy reactions functions (FRF) and (MRF), all depend on current and future variables only. This suggests the existence of an equilibrium where current play depends on current and future economic conditions only, thereby justifies taking as given future equilibrium play. If each period, in addition, monetary and fiscal policy are determined simultaneously,

Nash equilibrium requires taking the other players' decisions as given. This justifies the assumptions made in deriving (FRF) and (MRF) and motivates the following definition.

Definition 3 (SP) *A Markov-perfect Nash equilibrium with sequential monetary and fiscal policy is a sequence $\{c_t, h_t, \Pi_t, R_t, g_t\}$ solving equations (8), (9), (10), (FRF) and (MRF).*

We now show that assuming Stackelberg leadership by one of the policy authorities, instead of simultaneous decision making, would not affect the equilibrium outcome. While the policy problem of the Stackelberg follower remains unchanged, the Stackelberg leader should take into account the reaction function of the follower. Importantly, however, the Lagrange multipliers associated with additionally imposing either MRF in the sequential fiscal problem (15) or FRF in the sequential monetary problem (17) are zero. In fact, these reaction functions can be derived from the first order conditions of the leader's policy problem even when the follower's reaction function is not being imposed.

Intuitively, the leadership structure does not matter for the equilibrium outcome because the monetary and fiscal authorities are pursuing the same policy objective. Any departure of the equilibrium outcome from the Ramsey solution is thus entirely due to the assumption of sequential decision making. However, the presence of different policymakers and the sequence of moves will matter once we consider a monetary authority that is more inflation averse than the fiscal authority, in section 7.

4.4 Monetary and Fiscal Policy Interactions

This section analyzes how the fiscal spending bias and agents' utility is affected by the steady state inflation rate. Since steady state inflation depends on steady state nominal interest rates only, see equation (9), we implicitly analyze how the conduct of monetary policy affects fiscal policy and welfare. Appendix A.5 derives the following result.

Proposition 4 *Assume $u_{hh} < 0$. In a steady state with sequential fiscal policy, agents' utility increases and fiscal spending decreases with the steady state inflation rate, locally at $\Pi = 1$.*

The previous proposition implies that price stability ceases to be optimal once fiscal policy fails to commit to its spending plans. Intuitively, inflation increases the perceived costs of public spending for the fiscal authority, thereby reduces the fiscal spending bias. This makes it optimal to implement positive inflation rates.

The optimal inflation rate that appropriately internalizes the sequential fiscal policy distortion is obtained as a solution to the following problem⁸

$$\begin{aligned} \max_{\{c_t, h_t, \pi_t, R_t \geq 1, g_t\}} E_0 \sum_{t=0}^{\infty} \beta^t u(c_t, h_t, g_t) & \quad (\text{OI}) \\ \text{s.t.} & \\ \text{Equations (8),(9),(10),(FRF) for all } t & \end{aligned}$$

Here we assume that monetary policy can commit, but fiscal behavior is described by FRF. We will refer to this situation as the optimal inflation (OI) regime. If the optimal inflation rate is lower (higher) than the monetary inflation bias generated in a Markov-perfect Nash equilibrium with sequential monetary and fiscal policy, an inflation conservative (liberal) central bank would appear desirable. Whether the optimal inflation rate is above or below the monetary inflation bias is ultimately a quantitative issue. We address it in the next sections.

5 Model Calibration

To assess the quantitative relevance of the policy biases and the desirability of a conservative central bank, we assume the following preference specification

$$u(c_t, h_t, g_t) = \log(c_t) - \omega_h \frac{h_t^{1+\varphi}}{1+\varphi} + \omega_g \log(g_t) \quad (18)$$

which is consistent with balanced growth, where $\omega_h > 0$, $\omega_g \geq 0$ and $\varphi \geq 0$ denotes the inverse of the Frisch labor supply elasticity.

The baseline calibration of the model is summarized in table 1. The quarterly discount factor β is chosen to match the average ex-post U.S. real interest rate during the period 1983:1-2002:4, i.e., 3.5%. The steady state value for the price elasticity of demand η is set at -6 , implying a mark-up over marginal cost of 20%. The degree of price stickiness θ is chosen to be 17.5, such that the log-linearized version of the Phillips curve (8) is consistent with the estimates of Sbordone (2002), as in Schmitt-Grohé and Uribe (2004a). The elasticity of labor effort is assumed to be one ($\varphi = 1$) and we abstract from wasteful fiscal spending, i.e., $x = 0$. The utility weights ω_h and ω_g are chosen such that in the Ramsey steady state agents work 20% of their time ($h = 0.2$) and spend 20% of output on public goods ($g = 0.04$).⁹ The process for the technology shock z_t is

⁸As before, we abstract from non-stationary components of time zero optimal policies in the solution to (OI).

⁹The values of ω_h and ω_g are set according to equations (47) and (48), respectively, derived in appendix A.6.

taken from Schmitt-Grohé and Uribe (2004a).¹⁰ The parameterization for the mark-up shock process η_t is taken from Ireland (2004).¹¹

To test the robustness of our results, we consider also a range of alternative model parameterizations. For comparability, the utility weights ω_h and ω_g are adjusted so as to leave the Ramsey steady state unchanged.

The actual computational method we employ to numerically solve for the Markov-perfect Nash equilibrium with sequential monetary and fiscal policy is described in appendix A.7. A useful by-product of this approach is that it delivers second-order accurate welfare expressions for economies with a distorted steady state, while relying on linear-quadratic approximation only. This will be useful in section 8 when we analyze a stochastic economy.

6 Steady State Outcomes

Employing the baseline calibration summarized in table 1, we now investigate the quantitative impact of relaxing monetary and fiscal policy commitment. In addition, we compare the outcome under sequential policy (SP) to that achieved under the optimal inflation (OI) regime. Finally, we analyze the robustness of the quantitative findings to different model parameterizations.

The first row of table 2 presents information on the steady state in the SP regime. All variables are expressed as percentage deviations from their corresponding Ramsey steady state values.¹² The last column of the table reports the steady state welfare loss, expressed in terms of the permanent reduction in private consumption that would imply the Ramsey steady state to be welfare equivalent to the considered policy regime, see appendix A.8 for details. In line with proposition 2, the sequential policy outcome is characterized by an inflation bias, which turns out to be sizable. In addition, there is a small fiscal spending bias. Overall, the welfare losses generated by the sequential conduct of policy are sizable, in the order of 1% of steady state consumption per period.

The second row of table 2 shows the outcome under the OI regime. The optimal inflation rate turns out to be not only lower than the one in the SP regime but also very close to the Ramsey value. Note that reducing inflation from the level of the SP regime to the optimal level increases the fiscal spending bias, as suggested by proposition 4. While the fiscal spending increase associated with bringing down inflation is fairly large, implementing the optimal

¹⁰To transform the annual values reported in table 1 of Schmitt-Grohé and Uribe (2004a), we raise the AR-coefficient of the technology shock to the power 1/4 and divide the standard deviation of the shock innovation by 4.

¹¹Table 1 in Ireland (2004) presents estimates for the scaled mark-up shock process $\frac{\eta_t}{\theta}$. Multiplying his estimate for the standard deviation by our price adjustment cost $\theta = 17.5$ yields the standard deviation in our table 1. Ireland's estimate for the technology shock process is similar to the one used in this paper.

¹²In the Ramsey steady state $c = 0.16$, $h = 0.2$, $g = 0.04$ and $\Pi = 1$.

inflation rate nevertheless eliminates large part of the welfare losses associated with the SP regime. This suggests that the fiscal spending bias, despite being sizable in absolute value, is not very detrimental in welfare terms. Clearly, this result hinges partly on the assumed availability of lump sum taxes, which abstracts from deadweight losses typically associated with having to finance fiscal expenditure.¹³

The results from table 2 suggest that installing a conservative monetary authority is desirable - despite the lack of fiscal commitment - because the optimal inflation rate is well below the one emerging in the SP regime. Moreover, a conservative monetary authority can possibly eliminate large part of the welfare losses associated with sequential monetary and fiscal policymaking.

Table 3 explores the robustness of these findings to a wide range of changes in the parameterization of the model.¹⁴ The table reports the steady state welfare losses associated with the different policy regimes (first column) and the difference between inflation in the SP regime and the optimal inflation rate (second column). The previous findings seem fairly robust. In particular, significant welfare gains can be realized from implementing the optimal inflation rate. Exceptions are the flexible price limit ($\theta \rightarrow 0$) and the cases with inelastic labor supply (large values for φ), since the time-inconsistency problems of monetary and fiscal policy then disappear and real allocations approach the Ramsey steady state. The fact that all parameterizations display a positive inflation differential in the last column of table 3 suggests a conservative monetary authority should be desirable. We investigate this issue in detail in the next section.

7 Conservative Monetary Authority

This section analyzes whether the steady state distortions stemming from sequential monetary and fiscal policy decisions can be reduced by installing a central bank that is more inflation averse than society. Rogoff (1985) and Svensson (1997) have shown this to be the case if fiscal policy is treated as exogenous.

Following Rogoff (1985), we consider a ‘weight conservative’ monetary authority with period utility function

$$(1 - \alpha) u(c_{t+j}, h_{t+j}, g_{t+j}) - \alpha \frac{(\Pi_t - 1)^2}{2}$$

where $\alpha \in [0, 1]$ is a measure of monetary conservatism. For $\alpha > 0$ the monetary authority dislikes inflation (and deflation) more than society; if $\alpha = 1$ the

¹³A version of the model with distortionary labor taxes suggests that larger welfare losses are associated with lack of fiscal commitment.

¹⁴For all parametrization considered in table 3, the utility weights ω_h and ω_g are adjusted to leave the Ramsey steady state unchanged. When considering wasteful fiscal expenditure $c + x$, h and g are required to remain unchanged.

policymaker cares about inflation only. The preferences of the fiscal authority remain unchanged.

With monetary and fiscal authorities now pursuing different policy objectives, the equilibrium outcome will depend on the timing of policy moves, i.e., whether fiscal policy is determined before, after, or simultaneously with monetary policy. It remains to be ascertained, however, which of these timing structures is the most relevant for actual economies. While it may take long to implement fiscal policies, the time lag between a monetary policy decision and its effect on the economy can also be substantial. We thus consider Nash as well as leadership equilibria.

7.1 Nash and Leadership Equilibria

This section defines the various equilibria then briefly discusses them.

Consider the case of simultaneous policy decisions first. While the policy problem of the fiscal authority is unchanged, the monetary authority now solves

$$\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1\}} E_t \sum_{j=0}^{\infty} \beta^j \left((1-\alpha) u(c_{t+j}, h_{t+j}, g_{t+j}) - \frac{\alpha}{2} (\Pi_t - 1)^2 \right) \quad (19)$$

s.t.

Equations (8),(9),(10) for all t

$\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j-1}\}$ given for $j \geq 1$

As shown in appendix A.9, the first order conditions associated with problem (19) deliver the conservative monetary authority's reaction function

$$\begin{aligned} & - \frac{z_t u_{ct}}{u_{ht}} (\eta_t (\Pi_t - 1) - \Pi_t) - (\Pi_t - 1) \eta_t \left(1 + h_t \frac{u_{hht}}{u_{ht}} \right) \\ & + \left[2\Pi_t - 1 - \frac{u_{cct}}{u_{ct}} (\Pi_t - 1) (\theta (\Pi_t - 1) \Pi_t - z_t h_t (1 + \eta_t)) \right] \frac{(1-\alpha)\theta - \alpha \frac{z_t}{u_{ht}}}{(1-\alpha)\theta + \alpha \frac{1}{u_{ct}}} = 0 \end{aligned} \quad (\text{CMRF})$$

For $\alpha = 0$, CMRF reduces to the monetary reaction function without conservatism (MRF).¹⁵ This motivates the following definition.

Definition 5 (CSP-Nash) *A Markov-perfect Nash equilibrium with sequential and conservative monetary policy, sequential fiscal policy and simultaneous policy decisions is a sequence $\{c_t, h_t, \Pi_t, R_t, g_t\}$ solving (8), (9), (10), (FRF) and (CMRF).*

¹⁵As before, CMRF implies that current interest rates depend on current economic conditions only, validating the conjecture in (19) that in a Markov-perfect equilibrium future policy choices can be taken as given.

Next, we consider the case of monetary leadership (ML). The conservative monetary authority must take into account how the fiscal authority will react to its own decisions, i.e., FRF needs to be imposed as additional constraint. The monetary authority's policy problem at time t is thus given by

$$\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j \left((1 - \alpha) u(c_{t+j}, h_{t+j}, g_{t+j}) - \frac{\alpha}{2} (\Pi_{t+j} - 1)^2 \right) \quad (20)$$

s.t.

Equations (8),(9),(10),(FRF) for all t

$\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j}\}$ given for $j \geq 1$

The first order conditions associated with problem (20) deliver the conservative monetary reaction function with monetary leadership, that we denote by CMRF-ML. This gives rise to the following definition.

Definition 6 (CSP-ML) *A Markov-perfect equilibrium with sequential and conservative monetary policy, sequential fiscal policy and monetary policy deciding before fiscal policy is a sequence $\{c_t, h_t, \Pi_t, R_t, g_t\}$ solving (8), (9), (10), (FRF) and (CMRF-ML).*

Finally, we consider the case of fiscal leadership (FL). The fiscal authority must now take into account the conservative monetary authority's reaction, i.e., CMRF. The fiscal authority's policy problem at time t is thus given by

$$\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j u(c_{t+j}, h_{t+j}, g_{t+j}) \quad (21)$$

s.t.

Equations (8),(9),(10), (CMRF) for all t

$\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j} \geq 1, g_{t+j}\}$ given for $j \geq 1$

The first order conditions associated with problem (21) deliver the corresponding fiscal reaction function that we denote by CFRF-FL. We propose the following definition.

Definition 7 (SCMFP-FL) *A Markov-perfect equilibrium with sequential and conservative monetary policy, sequential fiscal policy, and fiscal policy deciding before monetary policy is a sequence $\{c_t, h_t, \Pi_t, R_t, g_t\}$ solving (8), (9), (10), (CFRF-FL) and (CMRF).*

We now briefly comment on the previous definitions. First, note that for the case $\alpha = 0$ all three equilibria reduce to the standard SP regime considered before in section 6. Second, for the Nash and monetary leadership cases, there

exists a theoretical upper bound on the welfare gains that monetary conservatism can possibly achieve. In these cases the fiscal authority takes monetary decisions as given, implying that FRF continues to describe fiscal behavior. The best possible allocation is thus described by the solution to the OI regime of section 4.4. Third, in the case with fiscal leadership, the fiscal authority anticipates the monetary reaction function. Monetary policy may then use ‘off-equilibrium’ behavior to discipline the behavior of the fiscal authority along the equilibrium path. Fiscal leadership thus opens the possibility for outcomes that are welfare superior to those achieved in the OI regime.

7.2 Implications of Central Bank Conservatism

Figure 1 displays the steady state welfare gains associated with different degrees of monetary conservatism $\alpha \in [0, 1]$, under the different leadership arrangements.¹⁶ The upper horizontal line shown in the figure indicates the welfare losses of the OI regime. Without monetary conservatism ($\alpha = 0$) all leadership arrangements deliver the welfare loss associated with the SP regime.

For the Nash and monetary leadership (ML) regimes, a fully conservative monetary authority ($\alpha = 1$) approximately implements the steady state welfare level associated with the OI regime.¹⁷ With an appropriate degree of monetary conservatism it is possible to recover the significant welfare losses resulting from lack of monetary commitment, in the order of 1% of steady state consumption per period. Interestingly, most of the welfare gains are achieved for values of α above 0.9, i.e., by a sufficiently conservative central bank caring almost exclusively about inflation.

The case for a conservative monetary authority is even stronger under the fiscal leadership (FL) regime. As shown in figure 1, a conservative monetary authority can recover not only the steady state welfare losses stemming from sequential monetary decision making, but also those emerging from lack of fiscal commitment. With full conservatism ($\alpha = 1$) the central bank recovers the Ramsey steady state. Again, most of the welfare gains are realized for values of α above 0.9.

Fiscal leadership differs from the Nash and monetary leadership cases because the fiscal authority anticipates the reaction of the conservative monetary authority. For $\alpha = 1$, the monetary authority is determined to implement price stability at all costs. A fiscal expansion above the Ramsey spending level would generate inflationary pressures, triggering a strong increase in interest rates so as to reduce private consumption. The fiscal authority anticipates that fiscal spending simply results in a crowding out of private consumption, this disciplines its behavior.

¹⁶This and subsequent figures use the baseline calibration of section 5.

¹⁷As will become clear from figure 2 below, the welfare level of the OI regime is actually achieved by a value of α very close but slightly below 1.

Figure 2 illustrates for the different leadership cases how the steady state values of private consumption, labor effort, inflation and public spending depend on the degree of monetary conservatism. While increased monetary conservatism reduces the inflation bias for all timing protocols, its effect on the fiscal spending bias depends on whether or not fiscal policy anticipates the monetary policy reaction. If fiscal policy takes monetary decisions as given, monetary conservatism results in an increased fiscal spending bias. With fiscal leadership, however, fiscal spending decreases to the Ramsey level as α increases towards 1. A value of $\alpha = 1$ recovers the Ramsey outcome in the FL regime, while a value of α slightly below one recovers the OI outcome in the Nash and ML regimes.

8 Conservatism and the Response to Shocks

Up to this point we have restricted attention to steady state outcomes. This section extends the analysis to a stochastic economy, considering how stabilization policy is affected by different monetary and fiscal policy regimes and the degree of monetary conservatism.

Figure 3 depicts impulse responses to a positive technology shock (left column) and positive mark-up shock (right column) for the case with commitment and under sequential policy.¹⁸ The figure illustrates that lack of monetary and fiscal commitment influences the impulse responses markedly. Under commitment inflation either reacts not at all (technology shocks) or just by a small amount (mark-up shocks). Instead, inflation increases by more and is also more persistent under sequential policy. Intuitively, positive technology shocks increase the temptation to boost the suboptimally low level of labor supply by ‘surprise inflation’, because labor input is temporarily more productive. Similarly, positive mark-up shocks temporarily increase the labor supply wedge, thereby also strengthen the incentives to raise labor input through additional fiscal spending.

Figure 4 clarifies how impulse responses are affected by installing an inflation conservative central bank. The figure depicts the Ramsey policy response together with the responses for the Nash and two leadership cases (ML and FL), assuming a fully conservative central bank focusing on inflation only ($\alpha = 1$). The left column of the figure shows that full monetary conservatism causes the sequential policy response to productivity shocks to be identical to the response under commitment, for all timing protocols. Full monetary conservatism implements the optimal stabilization policy in response to technology shocks, despite the sequential conduct of monetary and fiscal policy.

Next, consider the case of mark-up shocks, depicted in the right column of figure 4. Under fiscal leadership (FL) impulse responses deviate somewhat

¹⁸Using the baseline calibration of section 5 we consider a positive 3 standard deviation disturbance for the technology and mark-up shock values. Responses are presented in terms of percent deviations from steady state values.

from the Ramsey policy response, but deviations tend to be short-lived and smaller than in the case without conservatism, compare with figure 3. With monetary leadership (ML) or simultaneous policymaking (Nash) the situation is largely similar, except for the response of government spending, which then differs markedly from the Ramsey policy response. The discussion in section 6 suggests, however, that deviations of government spending from its optimal level do not have significant effects on welfare in the current setting.¹⁹

The previous findings suggest that monetary conservatism remains desirable in a stochastic economy because welfare effects tend to be dominated by steady state considerations. Moreover, monetary conservatism - quite surprisingly - also tends to improve the conduct of stabilization policy, especially in response to technology shocks. Clearly, further welfare gains could be achieved through even better stabilization policies.

9 Conclusions

This paper analyzes monetary and fiscal policy interactions in a dynamic stochastic general equilibrium model when policymakers lack the ability to credibly commit to policies ex-ante. It is shown that lack of fiscal commitment leads to excessive fiscal spending on public goods, while lack of monetary commitment results in the well-known inflation bias. The welfare losses generated by the sequential conduct of monetary and fiscal policy appear to be substantial.

While optimal monetary policy that appropriately internalizes the fiscal spending distortion implements positive inflation, we find the optimal inflation rate for our baseline calibration to be close to zero. Also, for a wide range of model parameterizations, the monetary inflation bias results larger than the optimal inflation rate, causing monetary conservatism to remain desirable in a situation with endogenous fiscal spending.

We find that large part of the steady state welfare losses associated with lack of monetary and fiscal commitment can be recouped, provided the monetary authority focuses exclusively on stabilizing inflation. Moreover, a fully conservative monetary authority also tends to improve the conduct of stabilization policy.

A number of important questions remain to be addressed in further research. In particular, for a positive description of monetary and fiscal policy interactions, it seems important to consider also distortionary taxation and government debt dynamics. These elements introduce additional interactions between monetary and fiscal policymakers that may have a major impact on the desirability of an inflation conservative monetary authority. We plan to extend the analysis to such richer settings in future work.

¹⁹Indeed, computing how consumption equivalent welfare losses depend on the degree of monetary conservatism α in a stochastic economy, results are virtually unchanged when compared to figure 1, which is based on a steady state comparison.

A Appendix

A.1 Ramsey Steady State

The Lagrangian of the Ramsey problem (12) is

$$\begin{aligned} & \max_{\{c_t, h_t, \Pi_t, R_t, g_t\}} E_0 \sum_{t=0}^{\infty} \beta^t \left\{ u(c_t, h_t, g_t) \right. \\ & + \gamma_t^1 \left[u_{ct}(\Pi_t - 1)\Pi_t - \frac{u_{ct}z_t h_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} \right) - \beta u_{ct+1}(\Pi_{t+1} - 1)\Pi_{t+1} \right] \\ & + \gamma_t^2 \left[\frac{u_{ct}}{R_t} - \beta \frac{u_{ct+1}}{\Pi_{t+1}} \right] \\ & \left. + \gamma_t^3 \left[z_t h_t - c_t - \frac{\theta}{2}(\Pi_t - 1)^2 - g_t - x \right] \right\} \end{aligned}$$

The first-order conditions w.r.t. $(c_t, h_t, \Pi_t, R_t, g_t)$, respectively, are given by

$$\begin{aligned} & u_{ct} + \gamma_t^1 \left(u_{cct}(\Pi_t - 1)\Pi_t - \frac{u_{cct}z_t h_t}{\theta} (1 + \eta_t) \right) \\ & - \gamma_{t-1}^1 u_{cct}(\Pi_t - 1)\Pi_t + \gamma_t^2 \frac{u_{cct}}{R_t} - \gamma_{t-1}^2 \frac{u_{cct}}{\Pi_t} - \gamma_t^3 = 0 \end{aligned} \quad (22)$$

$$u_{ht} - \gamma_t^1 \frac{u_{ct}z_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} + h_t \frac{u_{hht} \eta_t}{u_{ct} z_t} \right) + \gamma_t^3 z_t = 0 \quad (23)$$

$$(\gamma_t^1 - \gamma_{t-1}^1) u_{ct}(2\Pi_t - 1) + \gamma_{t-1}^2 \frac{u_{ct}}{\Pi_t^2} - \gamma_t^3 \theta(\Pi_t - 1) = 0 \quad (24)$$

$$-\gamma_t^2 \frac{u_{ct}}{R_t^2} = 0 \quad (25)$$

$$u_{gt} - \gamma_t^3 = 0 \quad (26)$$

where $\gamma_{-1}^j = 0$ for $j = 1, 2$. We denote the Ramsey steady state by dropping time subscripts. Equation (25), $u_{ct} > 0$ and $R_t \geq 1$ imply

$$\gamma^2 = 0$$

Equations (26) delivers

$$\gamma^3 = u_g > 0$$

This and equation (24) gives

$$\Pi = 1$$

From (9) it then follows

$$R = \frac{1}{\beta}$$

Then equation (8) delivers

$$1 + \eta + \frac{u_h}{u_c} \eta = 0 \quad (27)$$

This delivers (13) shown in the main text. Using the previous results, equation (23) simplifies to

$$u_h - \gamma^1 \frac{h}{\theta} u_{hh} \eta + u_g = 0 \quad (28)$$

From (22) one obtains

$$\gamma^1 \frac{h}{\theta} = \frac{u_c - u_g}{u_{cc} (1 + \eta)} \quad (29)$$

Substituting (29) into (28) delivers

$$u_h - \frac{u_c - u_g}{u_{cc} (1 + \eta)} u_{hh} \eta + u_g = 0$$

Using (27) to substitute for u_c one gets

$$u_g = -u_h \frac{1 + \left(\frac{\eta}{1+\eta}\right)^2 \frac{u_{hh}}{u_{cc}}}{1 + \frac{\eta}{1+\eta} \frac{u_{hh}}{u_{cc}}}$$

Using (27) again to substitute $\frac{\eta}{1+\eta}$ delivers (14) shown in the main text.

A.2 Sequential Fiscal Reaction Function

The fiscal problem (15) is

$$\begin{aligned} & \max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, g_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j \left\{ u(c_{t+j}, h_{t+j}, g_{t+j}) \right. \\ & + \gamma_{t+j}^1 \left[u_{ct+j} (\Pi_{t+j} - 1) \Pi_{t+j} - \frac{u_{ct+j} z_{t+j} h_{t+j}}{\theta} \left(1 + \eta_{t+j} + \frac{u_{ht+j} \eta_{t+j}}{u_{ct+j} z_{t+j}} \right) \right. \\ & \left. \left. - \beta u_{ct+j+1} (\Pi_{t+j+1} - 1) \Pi_{t+j+1} \right] \right. \\ & + \gamma_{t+j}^2 \left[\frac{u_{ct+j}}{R_{t+j}} - \beta \frac{u_{ct+j+1}}{\Pi_{t+j+1}} \right] \\ & \left. + \gamma_{t+j}^3 \left[z_{t+j} h_{t+j} - c_{t+j} - \frac{\theta}{2} (\Pi_{t+j} - 1)^2 - g_{t+j} - x \right] \right\} \end{aligned}$$

taking as given R_{t+j-1} and other variables dated $t+j$ for $j \geq 1$. The first order conditions w.r.t. (c_t, h_t, Π_t, g_t) , respectively, are given by

$$u_{ct} + \gamma_t^1 \left(u_{cct} (\Pi_t - 1) \Pi_t - \frac{u_{cct} z_t h_t}{\theta} (1 + \eta_t) \right) + \gamma_t^2 \frac{u_{cct}}{R_t} - \gamma_t^3 = 0 \quad (30)$$

$$u_{ht} - \gamma_t^1 \frac{u_{ct} z_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} + h_t \frac{u_{hht} \eta_t}{u_{ct} z_t} \right) + \gamma_t^3 z_t = 0 \quad (31)$$

$$\gamma_t^1 u_{ct} (2\Pi_t - 1) - \gamma_t^3 \theta (\Pi_t - 1) = 0 \quad (32)$$

$$u_{gt} - \gamma_t^3 = 0 \quad (33)$$

From equations (32) and (33) one gets

$$\gamma_t^1 = \frac{u_{gt}\theta(\Pi_t - 1)}{u_{ct}(2\Pi_t - 1)}$$

Using the previous result and (33) to substitute the Lagrange multipliers in (31) delivers FRF shown in the main text.

A.3 Sequential Monetary Reaction Function

The monetary problem (17) is

$$\begin{aligned} & \max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j \left\{ u(c_{t+j}, h_{t+j}, g_{t+j}) \right. \\ & + \gamma_{t+j}^1 \left[u_{ct+j}(\Pi_{t+j} - 1)\Pi_{t+j} - \frac{u_{ct+j}z_{t+j}h_{t+j}}{\theta} \left(1 + \eta_{t+j} + \frac{u_{ht+j}}{u_{ct+j}} \frac{\eta_{t+j}}{z_{t+j}} \right) \right. \\ & \left. \left. - \beta u_{ct+j+1}(\Pi_{t+j+1} - 1)\Pi_{t+j+1} \right] \right. \\ & + \gamma_{t+j}^2 \left[\frac{u_{ct+j}}{R_{t+j}} - \beta \frac{u_{ct+j+1}}{\Pi_{t+j+1}} \right] \\ & \left. + \gamma_{t+j}^3 \left[z_{t+j}h_{t+j} - c_{t+j} - \frac{\theta}{2}(\Pi_{t+j} - 1)^2 - g_{t+j} - x \right] \right\} \end{aligned}$$

taking as given g_{t+j-1} and other variables dated $t+j$ for $j \geq 1$. The first order conditions w.r.t. (c_t, h_t, Π_t, R_t) are given by

$$u_{ct} + \gamma_t^1 \left(u_{cct}(\Pi_t - 1)\Pi_t - \frac{u_{cct}z_t h_t}{\theta} (1 + \eta_t) \right) + \gamma_t^2 \frac{u_{cct}}{R_t} - \gamma_t^3 = 0 \quad (34)$$

$$u_{ht} - \gamma_t^1 \frac{u_{ct}z_t}{\theta} \left(1 + \eta_t + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t} \right) + \gamma_t^3 z_t = 0 \quad (35)$$

$$\gamma_t^1 u_{ct}(2\Pi_t - 1) - \gamma_t^3 \theta(\Pi_t - 1) = 0 \quad (36)$$

$$-\gamma_t^2 \frac{u_{ct}}{R_t^2} = 0 \quad (37)$$

Equation (37), $u_{ct} > 0$ and $R_t \geq 1$ imply

$$\gamma_t^2 = 0$$

Then solving (34), (35) and (36) for γ_t^3 delivers, respectively,

$$\gamma_t^3 = u_{ct} + \gamma_t^1 \left(u_{cct}(\Pi_t - 1)\Pi_t - \frac{u_{cct}z_t h_t}{\theta} (1 + \eta_t) \right) \quad (38)$$

$$\gamma_t^3 = -\frac{u_{ht}}{z_t} + \gamma_t^1 \frac{u_{ct}}{\theta} \left(1 + \eta_t + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t} \right) \quad (39)$$

$$\gamma_t^3 = \gamma_t^1 \frac{u_{ct}(2\Pi_t - 1)}{\theta(\Pi_t - 1)} \quad (40)$$

Equations (38) and (40) imply

$$\gamma_t^1 = \frac{\theta}{\frac{2\Pi_t-1}{\Pi_t-1} - \frac{u_{cct}}{u_{ct}} (\theta(\Pi_t - 1)\Pi_t - z_t h_t (1 + \eta_t))} \quad (41)$$

While equations (39) and (40) give

$$\gamma_t^1 = \frac{\theta}{\frac{z_t u_{cct}}{u_{ht}} \left(1 + \eta_t - \frac{2\Pi_t-1}{\Pi_t-1} + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t} \right)} \quad (42)$$

From (41) and (42) one obtains MRF shown in the main text.

A.4 Proof of Proposition 2

We first show that MRF cannot hold in the neighborhood of $\Pi = 1$. In steady state one can rewrite MRF as

$$\Pi \left(1 + \frac{u_c}{u_h} \right) + O(\Pi - 1) = 0 \quad (43)$$

where $O(\Pi - 1)$ summarizes terms that converge to zero as $(\Pi - 1) \rightarrow 0$. In a steady state with $\Pi = 1$ equation (8) delivers $1 + \eta + \frac{u_h}{u_c} \eta = 0$ and thus $\frac{u_c}{u_h} < -\frac{\eta}{1+\eta} < -1$. Since the implicit function $\frac{u_c}{u_h}(\Pi)$ defined by (8) exists, this implies that $1 + \frac{u_c}{u_h}$ is bounded away from -1 also in a sufficiently small neighborhood around $\Pi = 1$. Therefore, (43) cannot hold in the neighborhood of $\Pi = 1$. Moreover, from $R \geq 1$ and (9) we have $\Pi \geq \beta$ in steady state. For β sufficiently close to 1, it then follows that MRF can only hold if $\Pi > 1$.

A.5 Proof of Proposition 4

The effect of inflation on steady state utility is given by

$$\frac{du}{d\Pi} = u_c \frac{\partial c}{\partial \Pi} + u_h \frac{\partial h}{\partial \Pi} + u_g \frac{\partial g}{\partial \Pi} \quad (44)$$

where $c(\Pi), h(\Pi), g(\Pi)$ denote the steady state levels emerging under sequential fiscal policy when monetary policy implements inflation rate Π , and the derivatives u_j ($j = c, h, g$) are evaluated at this steady state. We first evaluate equation (44) at $\Pi = 1$. Equation (8) simplifies to

$$u_c = -\frac{\eta}{1 + \eta} u_h \quad (45)$$

Totally differentiating equation (10) and evaluating at $\Pi = 1$ gives

$$\frac{\partial c}{\partial \Pi} = \frac{\partial h}{\partial \Pi} - \frac{\partial g}{\partial \Pi}$$

Using this result and (16), equation (44) can be rewritten as

$$\frac{du}{d\Pi} = (u_c - u_g) \frac{\partial c}{\partial \Pi}$$

Equations (16) and (45) imply $u_c > u_g$, thus

$$\text{sign} \left(\frac{du}{d\Pi} \right) = \text{sign} \left(\frac{\partial c}{\partial \Pi} \right) \quad (46)$$

To determine the sign of $\partial c/\partial \Pi$ we totally differentiate equations (FRF), (8), (10) and evaluate at $\Pi = 1$, this delivers

$$\begin{pmatrix} 0 & -u_{hh} & -u_{gg} \\ \frac{h}{\theta} \eta \frac{u_h u_{cc}}{u_c^2} & -\frac{h}{\theta} \eta \frac{u_{hh}}{u_c} & 0 \\ -1 & 1 & -1 \end{pmatrix} \begin{pmatrix} \frac{\partial c}{\partial \Pi} \\ \frac{\partial h}{\partial \Pi} \\ \frac{\partial g}{\partial \Pi} \end{pmatrix} = \begin{pmatrix} h \eta \frac{u_h u_{hh}}{u_c} \\ 0 \\ 0 \end{pmatrix}$$

Solving for $\frac{\partial c}{\partial \Pi}$ and $\frac{\partial g}{\partial \Pi}$ gives

$$\begin{aligned} \frac{\partial c}{\partial \Pi} &= \frac{u_c u_{hh}}{u_c u_{hh} u_{gg} - u_{cc} u_h u_{gg} - u_{cc} u_h u_{hh}} h \eta \frac{u_h u_{hh}}{u_c} \\ \frac{\partial g}{\partial \Pi} &= \frac{-u_c u_{hh} + u_{cc} u_h}{u_c u_{hh} u_{gg} - u_{cc} u_h u_{gg} - u_{cc} u_h u_{hh}} h \eta \frac{u_h u_{hh}}{u_c} \end{aligned}$$

Assuming $u_{hh} < 0$, signing these expression delivers $\frac{\partial c}{\partial \Pi} > 0$ and $\frac{\partial g}{\partial \Pi} < 0$, as claimed. The former inequality and equation (46) imply $\frac{du}{d\Pi} > 0$, locally at $\Pi = 1$.

A.6 Utility Weights

For the period utility specification (18), the Ramsey policy marginal conditions (13) and (14), respectively, deliver

$$\omega_h = \frac{1}{ch^\varphi} \frac{1+\eta}{\eta} \quad (47)$$

$$\omega_g = \omega_h g h^\varphi \frac{1 + \frac{\eta}{1+\eta} \frac{c}{h} \varphi}{1 + \frac{c}{h} \varphi} \quad (48)$$

Assuming $c = 0.16$, $h = 0.2$, $g = 0.04$, $\eta = -6$ and $\varphi = 1$ one obtains the parameter values in table 1.

A.7 Solving for the Equilibrium with Sequential Monetary and Fiscal Policy

The Markov-perfect Nash equilibrium with sequential monetary and fiscal policy solves the following problem

$$\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j}, g_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j u(c_{t+j}, h_{t+j}, g_{t+j}) \quad (49)$$

s.t.

Equations (8),(9),(10) for all t

$E_t(c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j}, g_{t+j})$ given for $j \geq 1$

One should note that FRF and MRF need not be imposed, since they can already be derived from the first order conditions of this problem, see sections 4.3.1 and 4.3.2, respectively. Therefore, the solution of problem (49) will always satisfy FRF and MRF.

Then, the recursive formulation of the Lagrangian of problem (49) is

$$W(z_t, \eta_t) = \min_{(\gamma_t^1, \gamma_t^2, \gamma_t^3)} \max_{(c_t, h_t, \Pi_t, R_t, g_t)} \{f(\cdot) + \beta E_t W(z_{t+1}, \eta_{t+1})\} \quad (50)$$

s.t.

$$z_{t+1} = (1 - \rho_z) + \rho_z z_t + \varepsilon_{z,t+1}$$

$$\eta_{t+1} = \eta(1 - \rho_\eta) + \rho_\eta \eta_t + \varepsilon_{\eta,t+1}$$

where the one-period return is

$$f(\cdot) = u(c_t, h_t, g_t) + \gamma_t^1 \left[u_{ct}(\Pi_t - 1)\Pi_t - \frac{u_{ct}z_t h_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} \right) - E_t^{AS} \right] + \gamma_t^2 \left[\frac{u_{ct}}{R_t} - E_t^{IS} \right] + \gamma_t^3 \left[z_t h_t - c_t - \frac{\theta}{2}(\Pi_t - 1)^2 - g_t - x \right]$$

with the expectations functions

$$E_t^{AS} \equiv \beta E_t u_{ct+1}(\Pi_{t+1} - 1)\Pi_{t+1} \quad (51)$$

$$E_t^{IS} \equiv \beta E_t \frac{u_{ct+1}}{\Pi_{t+1}} \quad (52)$$

taken as given. The additional control variables γ_t^1 , γ_t^2 , γ_t^3 are the Lagrange multipliers associated with the implementability constraints (8) and (9), and the feasibility constraint (10), respectively.

We then solve for the steady state using the first order conditions of the recursive formulation (50). Thereafter, we compute a quadratic approximation of the one-period return $f(\cdot)$ around this steady state. This involves quadratically approximating the implementability and feasibility constraints. Instead, the expectation functions E_t^{AS} and E_t^{IS} are linearly approximated as

$$E_t^{AS} \approx a_0^1 + a_1^1(z_t - 1) + a_2^1(\eta_t - \eta) \quad (53)$$

$$E_t^{IS} \approx a_0^2 + a_1^2(z_t - 1) + a_2^2(\eta_t - \eta) \quad (54)$$

Importantly, postulating linear expectation functions is sufficient to obtain a first order approximation to the equilibrium dynamics and policy functions. The policymaker takes expectations functions as given, therefore, they do not show up in differentiated form in the first order conditions. Moreover, linear

expectations functions are sufficient to evaluate the Lagrangian, i.e., utility, up to second order. This is the case since either the implementability constraints or the associated Lagrange multipliers are zero in a sufficiently small neighborhood around the steady state. As a result, no first order terms appear when evaluating the quadratic approximation of $f(\cdot)$ at the solution. Obviously, this is just a restatement of the fact that (50) is an unconstrained optimization problem.

We now explain how we compute the expectation functions (53) and (54). We start with an initial guess for a_i^j ($j = 1, 2$; $i = 0, 1, 2$), then we solve (50) with $f(\cdot)$ replaced by its quadratic approximation. We update α_i^j , as explained below, and continue iterating until the maximum absolute change of the policy functions drops below the square root of machine precision, i.e., $1.49 \cdot 10^{-8}$.

Let the solution for the policy functions $c(\cdot)$ and $\Pi(\cdot)$ be given by

$$c_{t+1} - c = \delta_{cz} (z_{t+1} - 1) + \delta_{c\eta} (\eta_{t+1} - \eta) \quad (55)$$

$$\Pi_{t+1} - \Pi = \delta_{\Pi z} (z_{t+1} - 1) + \delta_{\Pi\eta} (\eta_{t+1} - \eta) \quad (56)$$

where variables without time subscript denote steady state values. A first order approximation of the expectation functions (51) and (52) then delivers

$$E_t^{AS} \approx E_t^{AS}|_{ss} + \frac{\partial E_t^{AS}}{\partial c_{t+1}} \Big|_{ss} E_t (c_{t+1} - c) + \frac{\partial E_t^{AS}}{\partial \Pi_{t+1}} \Big|_{ss} E_t (\Pi_{t+1} - \Pi)$$

$$E_t^{IS} \approx E_t^{IS}|_{ss} + \frac{\partial E_t^{IS}}{\partial c_{t+1}} \Big|_{ss} E_t (c_{t+1} - c) + \frac{\partial E_t^{IS}}{\partial \Pi_{t+1}} \Big|_{ss} E_t (\Pi_{t+1} - \Pi)$$

where $|_{ss}$ indicates expressions evaluated at steady state. These together with (55), (56) and

$$E_t (z_{t+1} - 1) = \rho_z (z_t - 1)$$

$$E_t (\eta_{t+1} - \eta) = \rho_\eta (\eta_t - \eta)$$

deliver the expectations functions consistent with the approximated policy functions

$$a_0^1 = \beta u_c (\Pi - 1) \Pi$$

$$a_1^1 = \beta \rho_z [(\Pi - 1) \Pi u_{cc} \delta_{cz} + u_c (2\Pi - 1) \delta_{\Pi z}]$$

$$a_2^1 = \beta \rho_\eta [(\Pi - 1) \Pi u_{cc} \delta_{c\eta} + u_c (2\Pi - 1) \delta_{\Pi\eta}]$$

$$a_0^2 = \beta \frac{u_c}{\Pi}$$

$$a_1^2 = \beta \frac{\rho_z}{\Pi} \left[u_{cc} \delta_{cz} - \frac{u_c}{\Pi} \delta_{\Pi z} \right]$$

$$a_2^2 = \beta \frac{\rho_\eta}{\Pi} \left[u_{cc} \delta_{c\eta} - \frac{u_c}{\Pi} \delta_{\Pi\eta} \right]$$

A.8 Consumption Losses Relative to Ramsey

Let $u(c, h, g)$ denote the period utility for the Ramsey steady state and let $u(c^A, h^A, g^A)$ represent the period utility for the steady state of an alternative

policy regime. The permanent reduction in private consumption that would imply the Ramsey steady state to be welfare equivalent to the alternative policy regime $\mu^A \leq 0$ is implicitly defined by

$$\begin{aligned} \frac{1}{1-\beta} u(c^A, h^A, g^A) &= \frac{1}{1-\beta} u(c(1+\mu^A), h, g) \\ &= \frac{1}{1-\beta} [u(c, h, g) + \log(1+\mu^A)] \end{aligned}$$

where the second equality uses equation (18). Therefore, one obtains

$$\mu^A = \exp [u(c^A, h^A, g^A) - u(c, h, g)] - 1$$

A.9 Conservative Monetary Reaction Function

The conservative monetary problem (19) is

$$\begin{aligned} &\max_{\{c_{t+j}, h_{t+j}, \Pi_{t+j}, R_{t+j}\}} E_t \sum_{j=0}^{\infty} \beta^j \left\{ (1-\alpha) u(c_{t+j}, h_{t+j}, g_{t+j}) - \frac{\alpha}{2} (\Pi_t - 1)^2 \right. \\ &+ \gamma_{t+j}^1 \left[u_{ct+j} (\Pi_{t+j} - 1) \Pi_{t+j} - \frac{u_{ct+j} z_{t+j} h_{t+j}}{\theta} \left(1 + \eta_{t+j} + \frac{u_{ht+j} \eta_{t+j}}{u_{ct+j} z_{t+j}} \right) \right. \\ &- \left. \beta u_{ct+j+1} (\Pi_{t+j+1} - 1) \Pi_{t+j+1} \right] \\ &+ \gamma_{t+j}^2 \left[\frac{u_{ct+j}}{R_{t+j}} - \beta \frac{u_{ct+j+1}}{\Pi_{t+j+1}} \right] \\ &\left. + \gamma_{t+j}^3 \left[z_{t+j} h_{t+j} - c_{t+j} - \frac{\theta}{2} (\Pi_{t+j} - 1)^2 - g_{t+j} - x \right] \right\} \end{aligned}$$

taking as given g_{t+j-1} and variables dated $t+j$ for $j \geq 1$. The first order conditions w.r.t. (c_t, h_t, Π_t, R_t) , respectively, are given by

$$(1-\alpha) u_{ct} + \gamma_t^1 \left(u_{cct} (\Pi_t - 1) \Pi_t - \frac{u_{cct} z_t h_t}{\theta} (1 + \eta_t) \right) + \gamma_t^2 \frac{u_{cct}}{R_t} - \gamma_t^3 = 0 \quad (57)$$

$$(1-\alpha) u_{ht} - \gamma_t^1 \frac{u_{ct} z_t}{\theta} \left(1 + \eta_t + \frac{u_{ht} \eta_t}{u_{ct} z_t} + h_t \frac{u_{hht} \eta_t}{u_{ct} z_t} \right) + \gamma_t^3 z_t = 0 \quad (58)$$

$$\gamma_t^1 u_{ct} (2\Pi_t - 1) - \gamma_t^3 \theta (\Pi_t - 1) - \alpha (\Pi_t - 1) = 0 \quad (59)$$

$$-\gamma_t^2 \frac{u_{ct}}{R_t^2} = 0 \quad (60)$$

Equation (60), $u_{ct} > 0$ and $R_t \geq 1$ imply

$$\gamma_t^2 = 0$$

Then solving (57), (58) and (59) for γ_t^3 delivers, respectively,

$$\gamma_t^3 = (1 - \alpha) u_{ct} + \gamma_t^1 \left(u_{cct}(\Pi_t - 1)\Pi_t - \frac{u_{cct}z_t h_t}{\theta} (1 + \eta_t) \right) \quad (61)$$

$$\gamma_t^3 = -(1 - \alpha) \frac{u_{ht}}{z_t} + \gamma_t^1 \frac{u_{ct}}{\theta} \left(1 + \eta_t + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t} \right) \quad (62)$$

$$\gamma_t^3 = \gamma_t^1 \frac{u_{ct}(2\Pi_t - 1)}{\theta(\Pi_t - 1)} - \frac{\alpha}{\theta} \quad (63)$$

Equations (61) and (63) imply

$$\gamma_t^1 = \frac{\theta \left(1 - \alpha + \frac{1}{u_{ct}} \frac{\alpha}{\theta} \right)}{\frac{2\Pi_t - 1}{\Pi_t - 1} - \frac{u_{cct}}{u_{ct}} (\theta(\Pi_t - 1)\Pi_t - z_t h_t (1 + \eta_t))} \quad (64)$$

While equations (62) and (63) give

$$\gamma_t^1 = \frac{\theta \left(1 - \alpha - \frac{z_t}{u_{ht}} \frac{\alpha}{\theta} \right)}{\frac{z_t u_{ct}}{u_{ht}} \left(1 + \eta_t - \frac{2\Pi_t - 1}{\Pi_t - 1} + \frac{u_{ht}}{u_{ct}} \frac{\eta_t}{z_t} + h_t \frac{u_{hht}}{u_{ct}} \frac{\eta_t}{z_t} \right)} \quad (65)$$

From (64) and (65) one obtains CMRF shown in the main text.

fiscal waste	$x = 0$
utility weight on labor effort	$\omega_h = 26.042$
utility weight on public goods	$\omega_g = 0.227$
technology shock persistence	$\rho_z = 0.95$
mark-up shock persistence	$\rho_\eta = 0.96$
quarterly s.d. technology shock innovation	s.d. $(\varepsilon_{zt}) = 0.006$
quarterly s.d. mark-up shock innovation	s.d. $(\varepsilon_{\eta t}) = 0.021$

Table 1: Baseline Calibration

Policy Regime	c	h	Π	g	Consumption Losses Relative to Ramsey SS
	(Deviations from Ramsey)				
SP	-0.44%	0.67%	1.46%	0.48%	-1.03%
OI	-0.83%	0.85%	0.09%	7.5%	-0.07%

Table 2: Steady State Effects

	Consumption Losses Relative to Ramsey SS		Inflation Differentials $\Pi^{SP} - \Pi^{OI}$ (Quarterly)
	OI	SP	
Baseline Calibration	-0.07%	-1.03%	1.37%
more competition ($\eta = -9$)	-0.03%	-0.21%	0.56%
less competition ($\eta = -3$)	-0.37%	-8.86%	4.49%
more sticky prices ($\theta = 50$)	-0.07%	-2.04%	1.19%
less sticky prices ($\theta = 5$)	-0.06%	-0.36%	1.34%
almost flexible prices ($\theta = 0.5$)	-0.03%	-0.05%	0.58%
very low labor supply elasticity ($\varphi = 8$)	-0.06%	-0.07%	0.07%
low labor supply elasticity ($\varphi = 3$)	-0.12%	-0.33%	0.53%
high labor supply elasticity ($\varphi = 0.1$)	-0.01%	-2.11%	2.17%
wasteful fiscal spending ($x = 0.05$)	-0.06%	-0.98%	1.12%

Figure 4: Impulse Responses With Full Conservatism ($\alpha = 1$)

European Central Bank Working Paper Series

For a complete list of Working Papers published by the ECB, please visit the ECB's website (<http://www.ecb.int>)

- 600 "A speed limit monetary policy rule for the euro area" by L. Stracca, April 2006.
- 601 "Excess burden and the cost of inefficiency in public services provision" by A. Afonso and V. Gaspar, April 2006.
- 602 "Job flow dynamics and firing restrictions: evidence from Europe" by J. Messina and G. Vallanti, April 2006.
- 603 "Estimating multi-country VAR models" by F. Canova and M. Ciccarelli, April 2006.
- 604 "A dynamic model of settlement" by T. Koepl, C. Monnet and T. Temzelides, April 2006.
- 605 "(Un)Predictability and macroeconomic stability" by A. D'Agostino, D. Giannone and P. Surico, April 2006.
- 606 "Measuring the importance of the uniform nonsynchronization hypothesis" by D. A. Dias, C. Robalo Marques and J. M. C. Santos Silva, April 2006.
- 607 "Price setting behaviour in the Netherlands: results of a survey" by M. Hoeberichts and A. Stokman, April 2006.
- 608 "How does information affect the comovement between interest rates and exchange rates?" by M. Sánchez, April 2006.
- 609 "The elusive welfare economics of price stability as a monetary policy objective: why New Keynesian central bankers should validate core inflation" by W. H. Buiter, April 2006.
- 610 "Real-time model uncertainty in the United States: the Fed from 1996-2003" by R. J. Tetlow and B. Ironside, April 2006.
- 611 "Monetary policy, determinacy, and learnability in the open economy" by J. Bullard and E. Schaling, April 2006.
- 612 "Optimal fiscal and monetary policy in a medium-scale macroeconomic model" by S. Schmitt-Grohé and M. Uribe, April 2006.
- 613 "Welfare-based monetary policy rules in an estimated DSGE model of the US economy" by M. Juillard, P. Karam, D. Laxton and P. Pesenti, April 2006.
- 614 "Expenditure switching vs. real exchange rate stabilization: competing objectives for exchange rate policy" by M. B. Devereux and C. Engel, April 2006.
- 615 "Quantitative goals for monetary policy" by A. Fatás, I. Mihov and A. K. Rose, April 2006.
- 616 "Global financial transmission of monetary policy shocks" by M. Ehrmann and M. Fratzscher, April 2006.

- 617 “New survey evidence on the pricing behaviour of Luxembourg firms” by P. Lünemann and T. Y. Mathä, May 2006.
- 618 “The patterns and determinants of price setting in the Belgian industry” by D. Cornille and M. Dossche, May 2006.
- 619 “Cyclical inflation divergence and different labor market institutions in the EMU” by A. Campolmi and E. Faia, May 2006.
- 620 “Does fiscal policy matter for the trade account? A panel cointegration study” by K. Funke and C. Nickel, May 2006.
- 621 “Assessing predetermined expectations in the standard sticky-price model: a Bayesian approach” by P. Welz, May 2006.
- 622 “Short-term forecasts of euro area real GDP growth: an assessment of real-time performance based on vintage data” by M. Diron, May 2006.
- 623 “Human capital, the structure of production, and growth” by A. Ciccone and E. Papaioannou, May 2006.
- 624 “Foreign reserves management subject to a policy objective” by J. Coche, M. Koivu, K. Nyholm and V. Poikonen, May 2006.
- 625 “Sectoral explanations of employment in Europe: the role of services” by A. D’Agostino, R. Serafini and M. Ward-Warmedinger, May 2006.
- 626 “Financial integration, international portfolio choice and the European Monetary Union” by R. A. De Santis and B. Gérard, May 2006.
- 627 “Euro area banking sector integration: using hierarchical cluster analysis techniques” by C. Kok Sørensen, J. M. Puigvert Gutiérrez, May 2006.
- 628 “Long-run money demand in the new EU Member States with exchange rate effects” by C. Dreger, H.-E. Reimers and B. Roffia, May 2006.
- 629 “A market microstructure analysis of foreign exchange intervention” by P. Vitale, May 2006.
- 630 “Implications of monetary union for catching-up member states” by M. Sánchez, May 2006.
- 631 “Which news moves the euro area bond market?” by M. Andersson, L. J. Hansen and S. Sebestyén, May 2006.
- 632 “Does information help recovering structural shocks from past observations?” by D. Giannone and L. Reichlin, May 2006.
- 633 “Nowcasting GDP and inflation: the real-time informational content of macroeconomic data releases” by D. Giannone, L. Reichlin and D. H. Small, May 2006.
- 634 “Expenditure reform in industrialised countries: a case study approach” by S. Hauptmeier, M. Heipertz and L. Schuknecht, May 2006.

- 635 “Identifying the role of labor markets for monetary policy in an estimated DSGE model” by K. Christoffel, K. Kuester and T. Linzert, June 2006.
- 636 “Exchange rate stabilization in developed and underdeveloped capital markets” by V. Chmelarova and G. Schnabl, June 2006.
- 637 “Transparency, expectations, and forecasts” by A. Bauer, R. Eisenbeis, D. Waggoner and T. Zha, June 2006.
- 638 “Detecting and predicting forecast breakdowns” by R. Giacomini and B. Rossi, June 2006.
- 639 “Optimal monetary policy with uncertainty about financial frictions” by R. Moessner, June 2006.
- 640 “Employment stickiness in small manufacturing firms” by P. Vermeulen, June 2006.
- 641 “A factor risk model with reference returns for the US dollar and Japanese yen bond markets” by C. Bernadell, J. Coche and K. Nyholm, June 2006.
- 642 “Financing constraints and firms’ cash policy in the euro area” by R. Pál and A. Ferrando, June 2006.
- 643 “Inflation forecast-based-rules and indeterminacy: a puzzle and a resolution” by P. Levine, P. McAdam and J. Pearlman, June 2006.
- 644 “Adaptive learning, persistence, and optimal monetary policy” by V. Gaspar, F. Smets and D. Vestin, June 2006.
- 645 “Are internet prices sticky?” by P. Lünnemann and L. Wintr, June 2006.
- 646 “The Dutch block of the ESCB multi-country model” by E. Angelini, F. Boissay and M. Ciccarelli, June 2006.
- 647 “The economic effects of exogenous fiscal shocks in Spain: a SVAR approach” by F. de Castro Fernández and P. Hernández de Cos, June 2006.
- 648 “Firm-specific production factors in a DSGE model with Taylor price setting” by G. de Walque, F. Smets and R. Wouters, June 2006.
- 649 “Monetary and fiscal policy interactions in a New Keynesian model with capital accumulation and non-Ricardian consumers” by C. Leith and L. von Thadden, June 2006.
- 650 “A structural break in the effects of Japanese foreign exchange intervention on yen/dollar exchange rate volatility” by E. Hillebrand and G. Schnabl, June 2006.
- 651 “On the determinants of external imbalances and net international portfolio flows: a global perspective” by R. A. De Santis and M. Lührmann, July 2006.
- 652 “Consumer price adjustment under the microscope: Germany in a period of low inflation” by J. Hoffmann and J.-R. Kurz-Kim, July 2006.
- 653 “Acquisition versus greenfield: the impact of the mode of foreign bank entry on information and bank lending rates” by S. Claeyns and C. Hainz, July 2006.
- 654 “The German block of the ESCB multi-country model” by I. Vetlov and T. Warmedinger, July 2006.

- 655 “Fiscal and monetary policy in the enlarged European Union” by S. Pogorelec, July 2006.
- 656 “Public debt and long-term interest rates: the case of Germany, Italy and the USA” by P. Paesani, R. Strauch and M. Kremer, July 2006.
- 657 “The impact of ECB monetary policy decisions and communication on the yield curve” by C. Brand, D. Buncic and J. Turunen, July 2006.
- 658 “The response of firms’ investment and financing to adverse cash flow shocks: the role of bank relationships” by C. Fuss and P. Vermeulen, July 2006.
- 659 “Monetary policy rules in the pre-EMU era: Is there a common rule?” by M. Eleftheriou, D. Gerdesmeier and B. Roffia, July 2006.
- 660 “The Italian block of the ESCB multi-country model” by E. Angelini, A. D’Agostino and P. McAdam, July 2006.
- 661 “Fiscal policy in a monetary economy with capital and finite lifetime” by B. Annicchiarico, N. Giammarioli and A. Piergallini, July 2006.
- 662 “Cross-border bank contagion in Europe” by R. Gropp, M. Lo Duca and J. Vesala, July 2006.
- 663 “Monetary conservatism and fiscal policy” by K. Adam and R. M. Billi, July 2006.
